Sample Calorimetry Problems with Answers

Let's explore some common problems with step-by-step solutions to deepen understanding.

Problem 1: Calculating Heat Absorbed or Released

Question:

A 50 g piece of iron at 150°C is dropped into 200 g of water at 25°C. Assuming no heat loss to the surroundings, what is the final temperature of the system? (Specific heat capacity of iron = 0.45 J/g°C; water = 4.18 J/g°C)

Solution:

Step 1: Assign knowns

- Mass of iron, $m_{\text{Fe}} = 50\text{ g}$
- Initial temperature of iron, $T_{\text{Fe,initial}} = 150^\circ\text{C}$
- Mass of water, $m_{\text{H}_2\text{O}} = 200\text{ g}$

- Initial temperature of water, $(T_{\text{H}_2\text{O},\text{initial}} = 25^\circ\text{C})$
- Specific heat of iron, $(c_{\text{Fe}} = 0.45\text{ J/g}^\circ\text{C})$
- Specific heat of water, $(c_{\text{H}_2\text{O}} = 4.18\text{ J/g}^\circ\text{C})$
- Final temperature, $(T_{\text{final}} = T)$ (unknown)

Step 2: Write heat transfer equations

- Heat lost by iron: $(Q_{\text{Fe}} = m_{\text{Fe}} c_{\text{Fe}} (T_{\text{Fe},\text{initial}} - T))$
- Heat gained by water: $(Q_{\text{H}_2\text{O}} = m_{\text{H}_2\text{O}} c_{\text{H}_2\text{O}} (T - T_{\text{H}_2\text{O},\text{initial}}))$

Step 3: Set heat lost = heat gained

$$m_{\text{Fe}} c_{\text{Fe}} (150 - T) = m_{\text{H}_2\text{O}} c_{\text{H}_2\text{O}} (T - 25)$$

Step 4: Plug in known values

$$50 \times 0.45 \times (150 - T) = 200 \times 4.18 \times (T - 25)$$

$$22.5 \times (150 - T) = 836 \times (T - 25)$$

Step 5: Expand and solve for T

$$22.5 \times 150 - 22.5 T = 836 T - 836 \times 25$$

$\backslash$

$$3375 - 22.5 T = 836 T - 20900$$

 $\backslash$

Bring all T terms to one side:

 $\backslash$

$$3375 + 20900 = 836 T + 22.5 T$$

 $\backslash$ $\backslash$

$$24275 = 858.5 T$$

 $\backslash$

Step 6: Calculate T

 $\backslash$

$$T = \frac{24275}{858.5} \approx 28.3^{\circ}\text{C}$$

 $\backslash$

Answer: The final temperature of the system is approximately 28.3°C.

Problem 2: Determining Specific Heat Capacity

Question:

A 100 g sample of a metal absorbs 500 J of heat and its temperature increases from 20°C to 60°C. Find the specific heat capacity of the metal.

Solution:

Step 1: Known quantities

- $(m = 100\text{ g})$
- $(Q = 500\text{ J})$
- $(\Delta T = 60^\circ\text{C} - 20^\circ\text{C} = 40^\circ\text{C})$

Step 2: Use heat transfer formula

[

$$Q = mc\Delta T$$

]

Step 3: Rearranged for (c)

[

$$c = \frac{Q}{m \times \Delta T}$$

]

Step 4: Calculation

[

$$c = \frac{500}{100 \times 40} = \frac{500}{4000} = 0.125\text{ J/g}^\circ\text{C}$$

]

Answer: The specific heat capacity of the metal is $0.125\text{ J/g}^\circ\text{C}$.

Problem 3: Calorimeter Calibration

Question:

A calorimeter contains 100 g of water at 20°C . When 50 g of steam at 100°C is condensed into the water, the final temperature of the mixture is 25°C . Find the calorimeter's heat capacity.

(Heat of condensation of steam = 2260 J/g ; Specific heat of water = $4.18\text{ J/g}^\circ\text{C}$)

Solution:

Step 1: Known data

- Mass of water in calorimeter, $(m_{\text{water}} = 100\text{g})$
- Initial water temperature, $(T_{\text{initial}} = 20^{\circ}\text{C})$
- Mass of steam, $(m_{\text{steam}} = 50\text{g})$
- Temperature of steam, $(T_{\text{steam}} = 100^{\circ}\text{C})$
- Final temperature, $(T_{\text{final}} = 25^{\circ}\text{C})$
- Heat of condensation, $(L = 2260\text{J/g})$
- Specific heat of water, $(c_{\text{water}} = 4.18\text{J/g}^{\circ}\text{C})$

Step 2: Calculate heat released by steam

- Heat released during condensation: $(Q_{\text{condensation}} = m_{\text{steam}} \times L = 50 \times 2260 = 113,000\text{J})$
- Heat released during cooling of condensed water from 100°C to 25°C :

$$[$$

$$Q_{\text{cooling}} = m_{\text{steam}} \times c_{\text{water}} \times (100 - 25) = 50 \times 4.18 \times 75 = 50 \times 313.5 = 15,675\text{J}$$

$$]$$

- Total heat released by steam:

$$[$$

$$Q_{\text{steam}} = Q_{\text{condensation}} + Q_{\text{cooling}} = 113,000 + 15,675 = 128,675\text{J}$$

$$]$$

Step 3: Heat absorbed by water and calorimeter

- Heat gained by initial water:

$$[$$

$$Q_{\text{water}} = m_{\text{water}} \times c_{\text{water}} \times (T_{\text{final}} - T_{\text{initial}}) = 100 \times 4.18 \times (25 - 20) = 100 \times 4.18 \times 5 = 2,090 \text{ J}$$

\]

- Let C_{cal} be the heat capacity of the calorimeter.
- Total heat absorbed by the system:

\[

$$Q_{\text{total}} = Q_{\text{water}} + C_{\text{cal}} \times (T_{\text{final}} - T_{\text{initial}}) = 2,090 + C_{\text{cal}} \times 5$$

\]

Step 4: Equate heat released

Calorimetry problems with answers are fundamental exercises in physics and chemistry that help students understand the principles of heat transfer, specific heat capacity, and caloric measurements. Mastering these problems enhances comprehension of how energy is conserved and transferred during physical and chemical processes. Whether you're studying for an exam or seeking to strengthen your problem-solving skills, this comprehensive guide will walk you through the concepts, steps, and examples to confidently tackle calorimetry problems with answers.

Understanding the Basics of Calorimetry

Before diving into problem-solving, it's essential to grasp the core concepts underpinning calorimetry:

What is Calorimetry?

Calorimetry is the science of measuring the amount of heat transferred during a physical or chemical process. It involves using a calorimeter—an insulated device—to prevent heat exchange with the surroundings, ensuring accuracy in measurements.

Key Concepts

- Heat (Q): Energy transferred due to temperature difference, measured in joules (J) or calories (cal).
- Specific Heat Capacity (c): The amount of heat required to raise the temperature of 1 gram of a

substance by 1°C.

- Mass (m): The amount of substance involved, usually in grams.
- Temperature Change (ΔT): The difference between initial and final temperatures, $\Delta T = T_{\text{final}} - T_{\text{initial}}$.
- Conservation of Energy: The heat lost by one substance equals the heat gained by another in an isolated system:

$$Q_{\text{lost}} = Q_{\text{gained}}$$

Common Types of Calorimetry Problems

Calorimetry problems typically involve scenarios such as:

- Heating or cooling substances
- Mixing substances at different temperatures
- Chemical reactions involving heat absorption or release
- Phase changes (melting, boiling)

Understanding the context helps determine the approach and the relevant formulas.

Step-by-Step Approach to Solving Calorimetry Problems

- Identify the Known and Unknown Values

List all given data: masses, initial and final temperatures, specific heats, heat of phase changes, etc.

- Choose the Appropriate Formula

The fundamental formula for heat transfer involving solids and liquids:

$Q = mc\Delta T$

$$Q = mc\Delta T$$

$Q = mL$

For phase changes:

$$Q = mL$$

$$Q = mL$$

$$Q = mL$$

Where L is the latent heat.

- Set Up Conservation of Energy Equation

For example, if one substance loses heat and another gains it:

$$Q_{\text{lost}} = Q_{\text{gained}}$$

$$Q_{\text{lost}} = Q_{\text{gained}}$$

$$Q_{\text{lost}} = Q_{\text{gained}}$$

- Solve for the Unknown

Rearrange the equation to find the unknown value, such as temperature change or mass.

- Check Units and Reasonableness

Ensure units are consistent, and the answer makes physical sense (e.g., temperature change isn't negative unless expected).

Sample Calorimetry Problems with Solutions

Example 1: Heating Water in a Calorimeter

Problem:

A 50 g sample of water at 20°C is heated in a calorimeter until its temperature reaches 80°C. The calorimeter itself has a heat capacity of 100 J/°C. Calculate the amount of heat energy supplied to the water and the calorimeter.

Solution:

Step 1:

Identify knowns:

- Mass of water, $(m_{\text{water}} = 50\text{g})$
- Specific heat of water, $(c_{\text{water}} = 4.18\text{J/g}^\circ\text{C})$
- Temperature change, $(\Delta T = 80^\circ\text{C} - 20^\circ\text{C} = 60^\circ\text{C})$
- Calorimeter heat capacity, $(C_{\text{cal}} = 100\text{J/}^\circ\text{C})$

Step 2:

Calculate heat absorbed by water:

$Q_{\text{water}} = mc\Delta T$

$$Q_{\text{water}} = mc\Delta T = 50\text{g} \times 4.18\text{J/g}^\circ\text{C} \times 60^\circ\text{C} = 50 \times 4.18 \times 60$$

$= 12,540\text{J}$

$Q_{\text{water}} = 50 \times 250.8 = 12,540\text{J}$

Step 3:

Calculate heat absorbed by the calorimeter:

$Q_{\text{cal}} = C_{\text{cal}}\Delta T$

$$Q_{\text{cal}} = C_{\text{cal}}\Delta T = 100\text{J/}^\circ\text{C} \times 60^\circ\text{C} = 6,000\text{J}$$

Step 4:

Total heat supplied:

$$Q_{\text{total}} = Q_{\text{water}} + Q_{\text{cal}} = 12,540\text{ J} + 6,000\text{ J} = 18,540\text{ J}$$

\\

Answer:

The total heat energy supplied to the system is approximately 18,540 Joules.

Example 2: Cooling Hot Metal in Water

Problem:

A 100 g piece of iron heated to 150°C is placed into 200 g of water at 25°C in a calorimeter with negligible heat capacity. Assuming no heat loss to surroundings, what is the final equilibrium temperature of the system?

Given:

- $m_{\text{Fe}} = 100\text{ g}$
- $c_{\text{Fe}} = 0.45\text{ J/g}^\circ\text{C}$
- $m_{\text{water}} = 200\text{ g}$
- $c_{\text{water}} = 4.18\text{ J/g}^\circ\text{C}$
- Initial temperatures: $T_{\text{Fe}} = 150^\circ\text{C}$, $T_{\text{water}} = 25^\circ\text{C}$

Solution:

Step 1:

Set the heat lost by iron equal to the heat gained by water:

\\

$$Q_{\text{Fe,lost}} = Q_{\text{water,gained}}$$

\\

\\

$$m_{\text{Fe}} c_{\text{Fe}} (T_{\text{initial,Fe}} - T_{\text{final}}) = m_{\text{water}} c_{\text{water}} (T_{\text{final}} - T_{\text{initial,water}})$$

\]

Step 2:

Plug in known values:

\[

$$100 \times 0.45 \times (150 - T_{\text{final}}) = 200 \times 4.18 \times (T_{\text{final}} - 25)$$

\]

\[

$$45 \times (150 - T_{\text{final}}) = 836 \times (T_{\text{final}} - 25)$$

\]

Step 3:

Expand both sides:

\[

$$45 \times 150 - 45 T_{\text{final}} = 836 T_{\text{final}} - 836 \times 25$$

\]

\[

$$6750 - 45 T_{\text{final}} = 836 T_{\text{final}} - 20,900$$

\]

Step 4:

Bring like terms together:

\[

$$6750 + 20,900 = 836 T_{\text{final}} + 45 T_{\text{final}}$$

\]

\[

$$27,650 = 881 T_{\text{final}}$$

\]

Step 5:

Solve for (T_{final}) :

\[

$$T_{\text{final}} = \frac{27,650}{881} \approx 31.36^{\circ}\text{C}$$

\]

Answer:

The final equilibrium temperature of the system is approximately 31.36°C .

Advanced Topics in Calorimetry

Phase Changes and Latent Heat

Problems involving phase transitions (melting, boiling) require incorporating latent heat:

\[

$$Q = mL$$

\]

Where:

- (L) is the latent heat (e.g., (L_{fusion}) , $(L_{\text{vaporization}})$)
- (Q) is the heat absorbed or released during the phase change.

Combining Phase Changes with Heating/Cooling

Often, problems involve multiple steps:

- Heating or cooling a substance to its phase change temperature.
- Melting or boiling.
- Heating or cooling the resultant phase.

In such cases, sum the heats:

$$Q_{\text{total}} = Q_{\text{heating}} + Q_{\text{phase change}} + Q_{\text{additional heating}}$$

Tips for Solving Calorimetry Problems

- Always write down all data clearly.
- Use consistent units throughout.
- Identify which substances are gaining or losing heat.
- Remember that heat lost by hot objects equals heat gained by cold objects in an isolated system.
- Include phase change calculations when relevant.
- Double-check your calculations for unit consistency and reasonableness.

Conclusion

Calorimetry problems with answers serve as a vital bridge between theoretical understanding and practical application of heat transfer principles. By systematically approaching these exercises—identifying knowns and unknowns, applying conservation of energy, and carefully performing calculations—you can develop strong problem-solving skills. Practice with diverse examples, including heating, cooling, mixing, and phase changes, will deepen your understanding and prepare you for more complex thermodynamic challenges.

Remember: The key to mastering calorimetry problems lies in understanding the principles, methodically setting up equations, and verifying your solutions. With consistent practice, you'll confidently tackle calorimetry questions in exams and real-world applications alike.

Question What is calorimetry and how is it used to solve heat transfer problems?
Answer Calorimetry is the measurement of heat transfer during physical or chemical processes. It is used to

solve heat transfer problems by applying the principle of conservation of energy, often using calorimeters to determine specific heat capacities, heat changes in reactions, or temperature changes in systems. How do you calculate the heat absorbed or released in a calorimetry problem? The heat absorbed or released is calculated using the formula $Q = mc\Delta T$, where m is mass, c is specific heat capacity, and ΔT is the change in temperature. For chemical reactions, the heat may also be calculated using enthalpy changes (ΔH) per mole of reactant or product. What are common assumptions made in calorimetry problems? Common assumptions include negligible heat loss to surroundings, the system is well-insulated, the specific heat capacities are constant over the temperature range, and the calorimeter's heat capacity is either negligible or known if it's a coffee cup calorimeter. How do you determine the temperature change in a calorimetry problem involving multiple substances? You set up an equation based on conservation of energy: the heat lost by one substance equals the heat gained by another. Using $Q = mc\Delta T$ for each substance, you can solve for the unknown temperature change, ensuring that the heat lost equals heat gained in the system. How is the heat capacity of a calorimeter factored into calorimetry calculations? The total heat capacity of the calorimeter (C) accounts for the calorimeter's ability to absorb heat. When considering the calorimeter, the total heat transfer is $Q = C\Delta T + mc\Delta T$ for the substances involved. If the calorimeter's heat capacity is known, it is included in the calculations to improve accuracy. What is the significance of the conservation of energy principle in calorimetry problems? The conservation of energy principle states that the total heat lost by hot substances equals the total heat gained by cold substances and the calorimeter. This principle is fundamental to solving calorimetry problems, allowing us to relate temperature changes to heat transfer without knowing the exact amount of heat exchanged. How do you approach a calorimetry problem involving a chemical reaction in solution? First, determine the amount of reactants involved and their molar enthalpy changes. Measure the temperature change of the solution, then use $Q = mc\Delta T$ to find the heat exchanged. Relate this to the molar enthalpy change to find the enthalpy of the reaction per mole. What are some common mistakes to avoid when solving calorimetry problems? Common mistakes include neglecting the heat capacity of the calorimeter, mixing units inconsistently, assuming temperature changes are negligible, ignoring heat loss to surroundings, and not accounting for molar quantities properly when dealing with chemical reactions.

Limitations and Considerations

While Sadiku's practice problems are highly valuable, some limitations are worth noting:

- Lack of Variability in Problem Contexts: Most problems are circuit analysis-focused, with less emphasis on modern power electronics or digital circuits.
- Solution Depth May Not Cover All Misconceptions: Some students might need additional resources for conceptual doubts.
- Potential Need for Supplementary Practice: Advanced topics or recent technological developments might require additional problem sets.

However, these limitations can be mitigated by integrating Sadiku's problems into a broader study plan.
